GCP - Carbon Budget 2010

opinion & comment

CORRESPONDENCE:

Rapid growth in CO₂ emissions after the 2008–2009 global financial crisis

To the Editor — Global carbon dioxide emissions from fossil-fuel combustion and cement production grew 5.9% in 2010, surpassed 9 Pg C (Pg C) for the first time, and more than offset the 1.4% decrease in 2009. The impact of the 2008–2009 global financial crisis (GFC) on emissions has been short-lived owing to strong emissions growth in emerging economies, a return to emissions growth in developed economies, and an increase in the fossil-fuel intensity of the world economy.

Preliminary estimates of global CO₂ emissions from fossil-fuel combustion and cement production show that emissions grew by 0.51 Pg C (5.9%) in 2010 and reached a record high of 9.1±0.5 Pg C (Supplementary Method). This is the highest total annual growth recorded, and the highest annual growth rate since 2003 (and previously 1973). The 2010 growth overcame the 1.4% drop in emissions recorded in 2009, which was due to the GFC, putting global CO₂ emissions back on the high-growth trajectory that persisted before the GFC (Fig. 1). Thus, after only one year, the GFC has had little impact on the strong growth trend of global CO₂ emissions that characterized most of the 2000s.

For the past two years (2009 and 2010), emissions growth has been dominated by the emerging economies (Supplementary Table S1). The CO₂ emissions in developed countries (which is taken as the Annex B countries from the Kyoto Protocol) decreased 1.3% in 2008 and 7.6% in 2009, but increased 3.4% in 2010, and are now lower than the average emissions during 2000–2007 (Fig. 2). The CO₂ emissions in developing countries (non-Annex B countries) increased 4.4% in 2008, 3.9% in 2009 and 7.6% in 2010; the GFC only causing a 40% decrease in emissions growth in 2009 compared with the trend since 2000 (Fig. 2). The 2010 growth was due to high growth rates in a few key emerging economies (Supplementary Table S1) — for example, China 10.4% (0.212 Pg C) and India 9.4% (0.049 Pg C) — although, the contribution from some developed countries was also significant in absolute terms: for example, United States 4.1% (0.060 Pg C), Russia Federation 5.9%

Figure 1 Global CO₂ emissions and carbon intensity. **a**, Emissions of CO₂ from fossil-fuel combustion and cement production for the world (Pg C yr⁻¹; black curve) and the carbon intensity of world GDP (g C per \$US 2000); red curve, inverted axis). The most important recent financial crises are highlighted with a linear trend fitted to the five years before the beginning of each crisis. **b–e**, CO₂ emissions (Pg C) for the regions most affected by each financial crisis (right axis) and the rest of the world (RoW; left axis). **b**, The oil crisis (1973) and the US savings and loans crisis (1990), where EEU is the 15 member states of the European Union as of 1995. **c**, The collapse of the Former Soviet Union (FSU; 1990). **d**, The Asian financial crisis (1997). **e**, The recent global financial crisis (2008–2009).

(0.025 Pg C) and the 27 member states of the European Union 2.3% (0.022 Pg C).

Recent decades, the growth in global CO₂ emissions can be explained mainly by the growth in economic activity corrected for decreases in the fossil-fuel carbon intensity (FPCI) of the global economy (fossil-fuel and industrial CO₂ emitted per US dollar of economic output, that is CO₂ per unit of gross domestic product (GDP))¹. Using constant-price GDP measured in purchasing power parities (real GDP), the FPCI decreased by 1.4% yr⁻¹ on average between 1980 and 2000. Since 2000 however, the FPCI has decreased by only 0.5% yr⁻¹ (Fig. 1), a sign that the positive trend of
