Key Highlights in 2023
Global fossil CO$_2$ emissions: 37.1 ± 2 GtCO$_2$ in 2022, 63% over 1990

Projection for 2023: 37.5 ± 2 GtCO$_2$, 1.1% [0.0% to +2.1%] higher than 2022

When including cement carbonation, the 2022 and 2023 estimates amount to 36.4 ± 2 GtCO$_2$ and 36.8 ± 2 GtCO$_2$ respectively.

The 2023 projection is based on preliminary data and modelling.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
There are sharp contrasts between the projected emissions changes for the top emitters.

The 2023 projections are based on preliminary data and modelling.

*Emissions from use of international aviation and maritime shipping bunker fuels are not usually included in national totals. Cement carbonation sink only included in global (World) estimate.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Land-use change emissions are $4.7 \pm 2.6 \text{ GtCO}_2$ per year for 2013–2022, and show a negative trend in the last two decades, but estimates are still highly uncertain. Projection for 2023: $4.1 \pm 2.6 \text{ GtCO}_2$

Estimates from three bookkeeping models
Source: Friedlingstein et al 2023; Global Carbon Project 2023
Land-use change emissions

Combined land-use change emissions from Brazil, Indonesia, and the Democratic Republic of the Congo make up 55% of the global net land-use change emissions.

Estimates from three bookkeeping models

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The global atmospheric CO₂ concentration is forecast to average 419.3 parts per million (ppm) in 2023, increasing by 2.4 ppm. A bigger increase is expected in 2024 when the current El Niño has full effect.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Atmospheric CO$_2$ concentration has increased every single year, including in 2020 – despite the drop in fossil CO$_2$ emissions – because of continued emissions.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The SSPs were designed to span the range of potential outcomes. Total CO₂ emissions are currently tracking in the middle of the range. The temperature outcomes are based on assessed scenarios in IPCC AR6 Working Group I.

This set of quantified SSPs are based on the output of six Integrated Assessment Models (AIM/CGE, GCAM, IMAGE, MESSAGE, REMIND, WITCH). Net emissions include those from land-use change and bioenergy with CCS.

Global fossil CO$_2$ emissions
Global fossil CO$_2$ emissions have risen steadily over the last decades. Emissions are set to grow again in 2023. When including cement carbonation, the 2023 estimate is $36.8 \pm 2$ GtCO$_2$. The 2023 projection is based on preliminary data and modelling. Source: Friedlingstein et al 2023; Global Carbon Project 2023.
Global fossil CO₂ emissions

For the last 100 years, it has generally taken a crisis to drive global emissions reductions. To stabilise temperatures, intentional, planned, sustained global reductions must begin.

The 2023 projection is based on preliminary data and modelling. Source: Friedlingstein et al 2023; Global Carbon Project 2023
Global CO₂ emissions growth has generally resumed quickly from global crises. Emission intensity has steadily declined but not sufficiently to offset economic growth.

Each trend line is based on the five years before the crisis and extended to five years after. Economic activity is measured in purchasing power parity (PPP) terms in 2017 US dollars.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Fossil CO$_2$ emissions by country
The top six emitters in 2022 covered 67% of global emissions: China 31%, United States 14%, India 8%, EU 7%, Russia 4%, and Japan 3%.

International aviation and maritime shipping (bunker fuels) contributed 2.8% of global emissions in 2022.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Countries have a broad range of per capita emissions reflecting their national circumstances.

Top emitters: Fossil CO$_2$ emissions per capita to 2022

International aviation and maritime shipping (bunker fuels) contributed 2.8% of global emissions in 2022.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Globally, decarbonisation and declines in energy per GDP are largely responsible for the reduced growth rate in emissions over the last decade. 2020 was a clear outlier with a sharp decline in GDP.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The USA and EU have the highest accumulated fossil CO$_2$ emissions since 1850, but China is a close third.
Fossil CO$_2$ emissions by source
Share of global fossil CO₂ emissions in 2023: coal (41%), oil (32%), gas (21%), cement (4%), flaring and others (2%, not shown)

The 2023 projection is based on preliminary data and modelling.
Source: Friedlingstein et al 2023; Global Carbon Project 2023
Global emissions from oil continued to rebound in both 2022 and 2023 with recovery of aviation. In 2022 natural gas declined because of supply constraints but returns to growth in 2023. Coal continues to climb.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Emissions by category from 2000 to 2023, with growth rates indicated for the more recent period of 2018 to 2023. Coal use has returned to growth, and both coal and oil declined sharply in the pandemic year 2020.

Global Annual Fossil CO₂ Emissions, 2000-23

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Consumption of natural gas declined in 2022, but oil recovered most of its pandemic-period losses. Renewable energy continued to grow, but needs to grow even faster to replace fossil energy consumption.

This figure shows “primary energy” using the substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38).

Source: Energy Institute 2023; Global Carbon Project 2023
Fossil CO$_2$ emission by source for top emitters
Fossil CO₂ emissions in China

China’s coal consumption continued to grow strongly in 2023, while emissions from oil recovered their losses from 2022’s COVID-19 lockdowns.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The USA’s emissions from coal are expected to drop again in 2023, to their lowest level since 1903, as the transition to natural gas continues. Emissions from oil are still below 2019’s level.

Source: EIA 2023; Friedlingstein et al 2023; Global Carbon Project 2023
India’s emissions continue to grow sharply in 2023. Increases in solar and wind capacity were far from sufficient to meet a large increase in power demand as the economy grows strongly.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The EU’s emissions from all three fossil fuels are expected to have declined in 2023, resulting from high prices and other economic headwinds on top of existing trends.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
In the Rest of the World, emissions from coal grow slightly while natural gas is flat. Oil in international aviation grew strongly again, but total oil in all other countries declined.

The Rest of the World is the global total less China, US, EU, and India.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Cement carbonation sink
Cement carbonation sink

The production of cement results in ‘process’ emissions of CO₂ from the chemical decomposition of carbonates. During its lifetime, cement re-absorbs some CO₂ from the atmosphere.

Global Fossil CO₂ Emissions and Uptake: Cement*

*Excludes fossil energy used to produce cement

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Land-use change emissions
Land-use change emissions are 4.7 ± 2.6 GtCO₂ per year for 2013–2022, and show a negative trend in the last two decades, but estimates are still highly uncertain.

Net land use emissions are the result of multiple anthropogenic activities on land that lead to CO₂ emissions or removals.

Estimates from three bookkeeping models
Source: Friedlingstein et al 2023; Global Carbon Project 2023
Emissions from permanent deforestation are 4.2 GtCO₂ per year for 2013–2022. Carbon dioxide removals through permanent af/reforestation are 1.9 GtCO₂ per year over the same period.

Estimates from three bookkeeping models
Source: Friedlingstein et al 2023; Global Carbon Project 2023
Regional patterns of land-use change emissions

Land-use emissions are high in the tropics, driven largely by deforestation. Net sinks occur in regions of re/afforestation such as parts of Europe and China.

The top three emitters over 2013–2022 – Brazil, Indonesia, and the Democratic Republic of the Congo – contribute 55% of the global net land-use emissions.

Estimates from three bookkeeping models

Budget Imbalance: 4%

(the difference between estimated sources & sinks)

-1.6 GtCO₂/yr

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Global carbon budget

Carbon emissions are partitioned among the atmosphere and carbon sinks on land and in the ocean. The “imbalance” between total emissions and total sinks is an active area of research.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The sinks have continued to grow with increasing emissions, but climate change will affect carbon cycle processes in a way that will exacerbate the increase of CO$_2$ in the atmosphere.

The budget imbalance is the total emissions minus the estimated growth in the atmosphere, land and ocean. It reflects the limits of our understanding of the carbon cycle.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Fossil emissions dominate in the Northern Hemisphere, while land-use emissions are important in the tropics. The North Atlantic and Southern Ocean are carbon sinks while the tropical ocean is a source of CO₂. Tropical, temperate and boreal forest are the main terrestrial carbon sinks.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The atmospheric concentration growth rate has increased steadily. The high growth in 1987, 1998, & 2015–16 reflect a strong El Niño, which weakens the land sink. The effects of the currently emerging El Niño are expected to be most visible in the growth rate in 2024.

Source: NOAA-GML; Friedlingstein et al 2023; Global Carbon Project 2023
The airborne fraction is the proportion of the total annual CO\textsubscript{2} emissions that remains in the atmosphere. The rest of the CO\textsubscript{2} emissions are removed by the land and ocean sinks. Around 45% of CO\textsubscript{2} emissions remain in the atmosphere despite sustained growth in CO\textsubscript{2} emissions.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
The ocean carbon sink, estimated by Global Ocean Biogeochemical Models and observation-based data products, amounts to 10.4 ± 1.5 GtCO$_2$/yr for 2013–2022 and 10.2 ± 1.5 GtCO$_2$/yr in 2022. The ocean CO$_2$ sink has not grown since 2019 due to a triple La Niña event during 2020–2022.

Source: SOCATv2023; Bakker et al 2016; Friedlingstein et al 2023; Global Carbon Project 2023
The land carbon sink, estimated by Dynamic Global Vegetation Models, was $12.3 \pm 3.1 \text{ GtCO}_2/\text{yr}$ during 2013–2022 and $13.9 \pm 3.0 \text{ GtCO}_2/\text{yr}$ in 2022. The total CO$_2$ fluxes on land (including land-use change) are also constrained by atmospheric inversions.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Process models suggest that increasing atmospheric CO$_2$ drives the land and ocean sinks while climate change reduces the carbon sinks; the climate effect is largest in tropical and semi-arid land ecosystems. Globally during the 2013–2022 decade, climate change reduced the land sink by $\sim$20% and the ocean sink by $\sim$7%.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Both atmospheric CO₂ inversions and atmospheric oxygen allow to estimate the land and ocean carbon fluxes, independently from the land and ocean process-based models, confirming the global carbon budget estimates of the land and ocean partitioning of anthropogenic CO₂.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Total land and ocean fluxes show more interannual variability in the tropics

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Large and unexplained variability in the global carbon balance caused by uncertainty and understanding hinder independent verification of reported CO₂ emissions.

The budget imbalance is the carbon left after adding independent estimates for total emissions, minus the atmospheric growth rate and estimates for the land and ocean carbon sinks using models constrained by observations.

Source: Friedlingstein et al 2023; Global Carbon Project 2023.

Positive values mean overestimated emissions and/or underestimated sinks.
The cumulative contributions to the global carbon budget from 1850
The carbon imbalance represents the gap in our current understanding of sources & sinks
The remaining carbon budget to limit global warming to 1.5°C, 1.7°C and 2°C is 275 GtCO₂, 625 GtCO₂, and 1150 GtCO₂ respectively, equivalent to 7, 15 and 28 years from 2024. 2590 GtCO₂ have been emitted since 1850.

The remaining carbon budget is the average of two estimates (IPCC AR6 and Forster et al., 2023), both updated by removing the most recent emissions. Quantities are subject to additional uncertainties e.g., future mitigation choices of non-CO₂ emissions.

Source: IPCC AR6 WG1; Forster et al., 2023; Friedlingstein et al. 2023; Global Carbon Project 2023.
Global CO₂ emissions must reach zero to limit global warming

Acknowledgements
The work presented in the Global Carbon Budget 2023 has been possible thanks to the contributions of hundreds of people involved in observational networks, modeling, and synthesis efforts.

We thank the institutions and agencies that provide support for individuals and funding that enable the collaborative effort of bringing all components together in the carbon budget effort.

We thank the sponsors of the GCP and GCP support and liaison offices.

We also want to thank the EU/H2020 project 4C (821003) that supported this coordinated effort as well as each of the many funding agencies that supported the individual components of this release. A full list is provided in Friedlingstein et al. 2023.

https://doi.org/10.5194/essd-15-5301-2023

We also thank the Fondation BNP Paribas for supporting the Global Carbon Atlas and the Integrated Carbon Observation System (ICOS) for hosting our data.

This presentation was created by Robbie Andrew and Pierre Friedlingstein with Pep Canadell, Glen Peters and Corinne Le Quéré in support of the international carbon research community.

Breakdown of global fossil CO₂ emissions by country

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Asia dominates global fossil CO₂ emissions, while emissions in North America are of similar size to those in Europe, and the Middle East is growing rapidly.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Fossil CO₂ emissions by continent: per capita

Oceania and North America have the highest per capita emissions, while the Middle East has recently overtaken Europe. Africa has by far the lowest emissions per capita.

Source: Friedlingstein et al 2023; Global Carbon Project 2023
Additional Figures

Consumption-based Emissions

Consumption–based emissions allocate emissions to the location that goods and services are consumed

Consumption-based emissions = Production/Territorial-based emissions minus emissions embodied in exports plus the emissions embodied in imports
Consumption-based emissions (carbon footprint)

Allocating fossil CO₂ emissions to consumption provides an alternative perspective. USA and EU are net importers of embodied emissions, China and India are net exporters.

Consumption-based emissions are calculated by adjusting the standard emissions estimates to account for international trade.

Source: Peters et al 2011; Friedlingstein et al 2023; Global Carbon Project 2023
Consumption-based emissions per person

The differences between fossil CO₂ emissions per capita is larger than the differences between consumption and territorial emissions.

Consumption-based emissions are calculated by adjusting the standard emissions estimates to account for international trade.

Source: Peters et al 2011; Friedlingstein et al 2023; Global Carbon Project 2023
Transfers of emissions embodied in trade between OECD and non-OECD countries grew slowly during the 2000’s, declined to 2015 and have been relatively flat since then.

‘All others’ includes all other countries along with emissions from international aviation and maritime shipping.

Historical cumulative emissions by continent

Cumulative fossil CO$_2$ emissions (1850–2022). North America and Europe have contributed the most cumulative emissions, but Asia is growing fast.

The figure excludes emissions from international aviation and maritime shipping.

Additional Figures

Energy Use
Energy use by source

Energy consumption by fuel source from 2000 to 2022, with growth rates indicated for the more recent period of 2017 to 2022.

This figure shows “primary energy” using the BP substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38).

Source: Energy Institute, 2023; Global Carbon Project 2023
Coal consumption in energy units has returned to peak levels, while consumption of all other energy sources is growing strongly.

This figure shows “primary energy” using the BP substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38).

Source: Energy Institute, 2023; Global Carbon Project 2023
Energy use by source: USA

Coal consumption has declined sharply in recent years with the shale gas boom and strong renewables growth. Output from nuclear power is slowly declining as stations are retired.

This figure shows “primary energy” using the BP substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38)

Source: Energy Institute, 2023; Global Carbon Project 2023
Pandemic year 2020 temporarily interrupted India’s strong growth in energy consumption. Consumption of coal and oil dominate.

This figure shows “primary energy” using the BP substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38).

Source: Energy Institute, 2023; Global Carbon Project 2023
Consumption of both oil and gas has rebounded in recent years, while coal continues to decline. Renewables are growing strongly, now providing more energy than nuclear power.

This figure shows “primary energy” using the BP substitution method (non-fossil sources are scaled up by an assumed fossil efficiency of approximately 0.38).
